Apoptosis

Apoptosis is a process by which cells are removed from the body at the end of their life span; it is necessary for the development and homeostasis and plays important roles in cancer and several neurodegenerative diseases. Apoptosis can be induced by external stimuli such as UV damage, irradiation, drug treatment and other factors including tumor necrosis factor (TNF). Regulation of apoptosis is highly conserved among species. Similar sets of genes cause apoptosis in both nematodes and humans. Most studied apoptotic genes are associated with p53 related genes, Bcl-2/Bax family, a family of cysteine proteases (caspases), caspase activated deoxyribonucleases, cytochrome C, and several members of the TNF super family. VARDA is continually developing Polyclonal and Monoclonal antibodies against key molecules involved in the apoptotic pathway.

NF-KB					

Nuclear factor kB (NF-kB) is a nuclear transcription factor that regulates expression of a large number of genes that are critical for the regulation of apoptosis, viral replication, tumorigenesis, inflammation and various autoimmune diseases. Composed of homo and heterodimers of five members of the Rel family including NF-kB1 (p50), NF-kB2 (p52), RelA(p65), RelB, and c-Rel (Rel), activation of NF-kB is thought to be part of a stress response as it is activated by a variety of stimuli including growth factors, cytokines, lymphokines, UV, pharmacological agents and stress. In its inactive form, NF-kB is sequestered in the cytoplasm, bound by members of the IkB family of inhibitor proteins, which include IkBa, IkBβ, IkBy, and IkBε. The various stimuli that activate NF-kB cause phosphorylation of IκB (through the IκB kinase complex consisting of at least three proteins: IKK1/α, IKK2/β and IKK3/γ), which is followed by its ubiquitination and subsequent degradation. This results in the exposure of the nuclear localization signals (NLS) on the NF-kB subunits and the subsequent translocation of the molecule to the nucleus. In the nucleus, NF-kB binds with consensus sequence (5'GGGACTTCC-3') of various genes, thus activating their transcription

Cytokine & Chemokine

Chemokines or chemotactic cytokines are small peptide molecules involved in the recruitment of leukocytes to sites of infection. These molecules are rapidly induced in response to various inflammatory and mitogenic stimuli. Some G Protein- coupled receptors including CCR5,CXCR4,CCR3,CCR2b and CCR8 in the chemokine receptor family and four new human molecules GPR15, STRL33, GPR1 and V28 were recently identified as HIV co-receptors. The absence of cell surface expression of the HIV co-receptor CCR5, due to a homozygous 32 base pair deletion, renders individuals highly resistant to infection by macrophage-tropic HIV strains. Chemokines and their receptors are attractive targets for the development of novel drugs for HIV therapies, inflammation and allergy.

Toll like receptors

Toll receptors were first discovered in the fruit fly *Drosophilla*; these receptors were shown to play a large role in innate immunity by recognizing microbial particles and activating immune cells against the source of these particles. Homologies of the *Drosophilla* Toll receptors are seen in mammalian immune cells; these receptors are termed Toll like receptors, and they play a similar role in microbial recognition. Currently ten Toll-like receptors have been identified, termed TLRs 1-13. The TLRs contain intracellular domains homologous to those of the IL-1 receptor and include extracellular leucine-rich repeats. Both the IL-1 receptor and the TLRs share similar downstream effects, such as the activation of immune response genes. These effects are initiated by the activation of MyD88 by the intracellular domains of the IL-1 and Toll-like receptors

Phosphospecific Antibodies

Protein phosphorylation is a major mechanism that regulates protein activity in the cell. It is involved both directly and indirectly in regulating nearly all cellular processes where it serves as a molecular "switch" to turn protein activity on and off through cycles of phosphorylation/ dephosphorylation events. Establishing that protein phosphorylation is a mechanism of cellular regulation in a particular system includes showing that the protein is phosphorylated, that the phosphorylation event changes the activity of the protein and defining which amino acid(s) in the protein that the phosphate moiety is attached. Phosphospecific antibodies have emerged as key tools for studying phosphorylation events by a variety of techniques including western blot, ELISA, flow cytometry and immunohistochemical analysis. These antibodies are directed specifically against phosphorylated antigens and a key attribute is that they do not recognize the unphosphorylated form of the protein

ChIP Assays & Components

Chromatin Immunoprecipitation (ChIP) is a powerful method used to identify regions of the genome associated with specific proteins. These associations are crucial for vital cellular functions including gene transcription, DNA Replication, recombination, repair, segregation, chromosomal stability, cell cycle progression and epigenetic silencing. The ChIP assay has been used to study both histones and non-histone proteins, such as transcription factors, within the context of the cell. Transcription factors and other DNA binding proteins have weaker affinity than histones, which generally are tightly associated with the chromatin complex. To avoid dissociation of non histone proteins from the chromatin binding site, it's necessary to incorporate a cross link step such as formaldehyde to cross link proteins to DNA.

After cross linking occurs, the chromatin are released from the nuclei and sheared into 200-1000bp fragments. The chromatin are then immunoprecipitated with specific antibodies. DNA sequences cross linked to the protein of interest co-precipitate as part of the chromatin complex. The DNA/chromatin/antibody complex is then isolated using protein G Agarose. After reverse crosslinking, the associated DNA is released from the complex and is ready for analysis.

Histo - Array™ Slides					
By arraying large numbers of tissues on a slide, one can more easily evaluate and correlate gene and protein expression across hundreds of samples. This translates to significant savings in time through elimination of tissue acquisition, as well as money due to reduced reagent usage. Additionally, tissue arrays are compatible with many high throughput analysis systems allowing even faster data acquisition and analysis. VARDAs Histo-Array tissue array slides are ideal for protein and <i>insitu</i> mRNA expression screening application and studies. Practical innovative, inexpensive, yet highly efficient each formalin or methanol fixed Histo-Array tissue array slide contains upto sixty defined tissue samples and include relevant patient information. Available in a number of tissue themes, including matched normal and cancerous tissue sets. VARDAs Histo Array tissue array slides represent a powerful tool for scientists in all areas to speed up research while minimizing reagents and labor costs.					
Tissue Microarrays					

Generating your own tissue and cell lysates cannot only be expensive and time consuming, but if done improperly can create misleading data. Yet finding a high quality and reliable source for lysates for your research! We use only the highest quality starting materials and test each lysate with our own reference antibodies. So you are sure to get consistent result-time after time.
